## PATENT APPLICANT

A.I.Rajasingham, 6024 Bradley Boulevard, Bethesda MD 20817. Tel: 301 229 0218.

**TITLE OF INVENTION:** Easy Ejector Seat with Skeletal Crash Safety Beam .

**CROSS REFERENCE TO RELATED APPLICATIONS:** This application is a continuation in part of the application entitled "Easy Ejector with skeletal crash safety beam" US S/N: 08/936,626 filed 9/24/97, US S/N 09/404,475, US S/N 09/435,830 and claims priority from US S/N: 08/936,626 filed 9/24/97, US S/N 09/404,475, US S/N 09/435,830, US S/N 60/195298, US S/N 60,226,570, EPO S/N 98948260.9-2306, EPO S/N 00203896.6.

## STATEMENT REGARDING

**FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT:** Not Applicable

**REFERENCE TO A MICRO FICHE APPENDIX:** Not Applicable

## BACKGROUND OF INVENTION

### FIELD OF INVENTION

The present invention defines a means to incorporate in passenger motor vehicles, unique safety arrangements particularly for lateral or side impacts that provide energy absorption by the mass of the vehicle but decouple the passenger from the impact acceleration and deceleration that is provided by the mass of the vehicle, thereby protecting the passengers during such collisions. Moreover, the same arrangement synergistically provides utility in access, comfort and further safety in the operating position for passengers and the driver.

### DESCRIPTION OF THE RELATED ART:

In the past safety of passengers was not always the priority in passenger vehicle design. In the evolution of motor vehicle design the structure moved from a chassis that held together the mechanical components of the vehicle – a structure that was then attached to a passenger compartment or to passenger seats.

1 The design of the structure was to hold together the working components of the vehicle – a critical aspect at the  
2 time. Thereafter in more recent times right up to the present, Exo-skeletal designs have been the dominant  
3 paradigm. Here rigid shells were constructed to hold both the mechanical components and the passengers in  
4 fixed positions. However such fixed shell structures have had limited success in protecting passengers and  
5 drivers when there are lateral collisions as passengers undergo the same impact related accelerations and  
6 decelerations as the remaining parts of the vehicle, as space limitations don't allow for "crumple zones" as in the  
7 case of impact protection for head on collisions. Passengers are particularly vulnerable to side impacts as they  
8 cannot take preemptive measures as with head-on collisions where there is speed control and directional control  
9 that is available. As vehicle speeds have increased substantially in the last several decades, these safety  
10 considerations for passengers have become critical and urgent. Vehicle designers — particularly automobile  
11 designers – have risen admirably to the task by incorporating myriads of devices and additions within the rigid  
12 shell paradigm to minimize risk in the event of collisions. Such devices include restraints such as seat belts and  
13 certain types of protective air bags. However, there are limits within the rigid shell paradigm for two reasons:  
14 First, the energy of impact cannot be easily diverted away from passengers into the remaining mass of the vehicle  
15 on impact. Second, the rigid shell needs to support high shear stresses on lateral impact and related compressive  
16 loads to the passenger compartment of the vehicle a factor that can only be addressed with greater mass of the  
17 vehicle that will impact its performance.

18 Another area of interest in passenger vehicles is to provide, in synergy with the above  
19 contributions, utility and comfort of passengers and drivers and further synergistic head-on collision protection.

20 There are four areas of Background art that are related to the present invention. These are:  
21 vehicles with sliding seats, safety arrangements addressing lateral impacts on passenger vehicles, air bags and  
22 other shock absorbing devices, and miscellaneous safety devices for frontal impacts. None of the inventions in  
23 these areas individually or collectively state or imply any aspects of the present invention. Moreover, none of this  
24 Background art even addresses the issue of energy transfer away from the passengers to the mass of the vehicle  
25 on impact and concurrently provide a mechanism for easy access to the vehicle with ejector seats. This is despite  
26 the urgent need in the car industry for such safety and utility. Moreover the novelty of the present invention is  
27 underscored as it provides solutions hitherto unidentified in a very large and competitive industry that is acutely  
28 aware of these needs and is constantly in search of new solutions to them.

29  
30 Sloan 3,071,407 (1963) describes a single rear bench seat ( lines 4-45) – full length (C1-  
31 L55), that can slide out of either side of the vehicle. It describes a door structure that may be attached to the seat  
32 and slide across and through the passenger compartment of the vehicle as the seat slides out. This invention does  
33 not state or imply any safety considerations in its structure, moreover such a bench seat on slides, in the event of  
34 a lateral collision on the doors will focus the impact energy on the passengers and these passengers will be the  
35 principal casualties as the mass of the vehicle slides away little harmed. This will be the case even in the  
36 embodiment described where the doors are fixed to the seat and slides through the passenger compartment with  
37 the seat. Moreover, it cannot be used in a front seat even for its limited functionality with doors fixed to the seat  
38 as driving instrumentation (steering wheel etc) will not allow a door to slide through the compartment. Finally it  
39 does not provide any comfort features for passengers over and above a bench seat. Mach 2,753,947 (1956)

1 describes a sliding bench seat for the access of the engine of the vehicle it does not address the issue of safety of  
2 passengers or access utility. It is expected to perform similarly to Sloan in an impact on the doors or around the  
3 side profile of the passengers in the vehicle. Solomon 2,758,872 (1953) provides a sliding bench seat that goes  
4 through the doorway and for the same reasons as Sloan does not provide protection in side impacts or provide  
5 any comfort features over and above a bench seat. Cyphert 3,944,277 (1976) describes a seat mounted on a  
6 sliding platform that has a door at the end and protective walls around it. The arrangement being designed for the  
7 utility of the operator to reach points away from the body of the vehicle without dismounting the vehicle. This  
8 invention like Sloan does not state or imply any safety considerations in its use. Moreover there is no expressed  
9 or implied reference to the utility of mounting and dismounting the vehicle or for the comfort of the operator or  
10 the passengers except for the ability for the platform to move out to give the operator greater reach away from  
11 the vehicle body. Rees 5,213,300 (1993) describes internal design structure for slide arrangements that allow  
12 forward and backward movement of the passenger seats in vehicles. This like many other inventions prior to it  
13 relate to the structure of the slides to adjust the position of the seats for passenger comfort in the direction of  
14 motion of the vehicle.

15 All the above items of background art relate to sliding seats. None of the above  
16 background art related to sliding seats have stated or implied safety considerations. Moreover, none of them  
17 provide utility for mounting and dismounting a vehicle except for a bench seat that slides out on either side of the  
18 vehicle, or provide comfort features except for seating arrangement on a bench seat and in one of the above – the  
19 lateral movement for convenience of the operator.

20  
21 Maier US 2,148,950 (1939) provides a laterally braced passenger compartment that  
22 braces a rigid shell body of a vehicle. Barenyi 2,710,222 (1955) provides a stiffening for the bottom plate of a  
23 vehicle body. Catlin 5,660,428 (1997) provides a design for a rigid shell structure. Guertler 5,464,266 (1995)  
24 uses stiffening arrangements for the floor of the vehicle as a component of a rigid shell vehicle body. Masuda  
25 5,671,968 (1968) describes a strengthened rigid shell for the passenger compartment. Oliver 4,533,172 (1985)  
26 describes a three part rigid shell structure for motor vehicles with the central section for passengers. Sinnhuber  
27 5,000,509 (1991) describes an arrangement that transfers impact energy from lateral impacts to the rigid body of  
28 the vehicle but does so through rigid members that include elements in the seats. The seats have limited lateral  
29 movement and are not free to move independent of the vehicle body in the event of a collision, thereby placing  
30 the passengers on the direct path of the energy transfer. Maeda 4,512,604 (1985) describes a lateral brace for the  
31 seat arrangement of the vehicle within a rigid vehicle body structure thereby distributing the impact energy to  
32 other parts of the rigid body structure. Sacco 5,435,618 (1995) describes a lateral stiffening element that braces  
33 the rigid vehicle body in the region of the seats. Bhalsod 5,716,094 (1998) describes a pusher block that  
34 engages the seat in the event of a lateral impact thereby providing a rigid member between the rigid body  
35 structure and the seats that can transfer impact energy to the seats.

36 All of the above items of background art related to bracing a rigid body structure and  
37 provide stiffening mechanisms within the rigid shell structure to distribute energy of lateral impact. None of  
38 these items of background art provide mechanisms to transfer energy away from passengers in lateral impacts. or

1 provide other safety arrangements or provide utility for mounting and dismounting the vehicle or provide  
2 comfort features for passengers in the operating position.

3

4 Baber 5,725,265 (1998) presents airbags for front and rear vehicle bumpers that deploy  
5 on impact. Such devices cannot be implemented on the side of the vehicle as a deceleration zone is not available  
6 under operating conditions as may be made available in the front and back of the vehicle. Moreover, as this  
7 airbag deploys on impact it creates a deceleration zone by pushing its own vehicle away that may actually  
8 increase the impulse forces acting on the passengers. Mercier 3,822,076 (1974) describes similar external front  
9 and back airbags and uses probes that protrude from the vehicle at the front and back to deploy the airbags. Such  
10 apparatus cannot be installed on the sides of the vehicle, as clearances are small. Stirling 5,131,703 (1992)  
11 describes a fluid filled chamber around the vehicle that will provide a deceleration zone on impact – frontal rear  
12 or lateral. However this arrangement requires the deceleration zone to be present during normal operating  
13 conditions that will reduce the maneuverability of vehicles if deployed on the sides of the vehicle. Park  
14 4,995,659 (1991) describes a gas filled chamber deployed around the vehicle. Such a chamber is normally  
15 inflated under normal conditions and reduces maneuverability of the vehicle. Campbell 4,815,777 (1989)  
16 describes a bumper that can be deployed selectively by filling with gas. This bumper is effective when extended  
17 only. It is not designed to be deployed when the vehicle is in motion, as it will reduce maneuverability.  
18 Hartmann 5,810,427 (1998) describes a mechanism that transfers fluid from one airbag to another on impact.  
19 The airbag that is deployed is normally in an extended position to absorb the impact energy and provide the  
20 deceleration zone. However, such an extended airbag will reduce the maneuverability of the vehicle. There is a  
21 literature (“Extended Bumper and Glass-Plastic glazing methods to reduce intrusion and ejection in severe motor  
22 vehicle crashes”. C.C.Clark 1993. 26th Symposium on Automotive Technology and Automation. Aachen  
23 Germany., “Airbag bumpers inflated just before the crash” C.C.Clark., William A. Young. 1994. SAE Technical  
24 Paper 941051., “The crash anticipating extended airbag bumper system”. C.C.Clark.1994. Fourteenth  
25 International Technical Conference on the enhanced safety of vehicles. Munich Germany., “Airbags as a means  
26 to reduce crash loads and intrusion, and increase inter-vehicular compatibility.” C.C.Clark. 1995. International  
27 Conference on Pelvic and Lower extremity injuries-Proceedings Washington DC., Human Transportation  
28 Fatalities and Protection against Rear and Side Crash Loads by the Airstop Restraint” Carl Clark and Carl  
29 Blechschmidt. 1965. The Ninth Stapp Car Conference.) IDS, and background art on the construction of external  
30 airbags including deployment proactively with radar or other devices. This entire literature is limited to the use  
31 of proactive external airbags mounted on vehicles with rigid structures that include the passenger. There is no  
32 reference in this literature to the proactive detection of impact explicitly or implicitly creating a deceleration  
33 zone for passenger protection internally, relative to the vehicle as in the present invention. Moreover, this  
34 literature is focussed on external airbags for front impact protection with for example rigid penetration buffers to  
35 negotiate posts and trees, unlike the present invention which does not prescribe external airbags for front  
36 impacts. Furthermore, as this literature describes external airbags without perforation shields their  
37 implementability is questionable as, unlike internal airbags that are in relatively protected environments, impact  
38 with external airbags often occurs with objects with sharp points and edges that are likely to perforate the  
39 external airbags. The Present invention requires perforation shields for external airbags.

1                   All the above items of background art relate to air bag devices for safety in vehicles.  
2         However, none of these references take the integrated approach of the present invention, as more fully explained  
3         below, which comprises proactive deployment of both internal and external air bags, together with sliding seat  
4         members and other devices. Moreover while the present invention can function even without the deployment of  
5         external airbags, either proactive or reactive, taken together these items provide protection for passengers which  
6         is more than the sum of the parts. Furthermore, none of the protection airbags disclosed, related to external air  
7         bags having protective perforation shields that further enhance their efficacy. Moreover none of these devices  
8         provide energy transferring mechanisms away from the passenger in a lateral impact or provide other safety  
9         features. Moreover they do not provide any utility features for passengers in mounting and dismounting the  
10        vehicle or provide comfort features to the passengers.

11  
12                   Perras 2,873,122 (1959) which describes an invention where upon a head-on collision the  
13         seat projects a curved protector around the passenger designed to protect the passenger. This curved protector  
14         retracts into the seat under normal operating conditions. It is not clear how effective such a mechanism will be as  
15         the acceleration of the passenger forward relative to the vehicle may precede that of curved protector's release  
16         from the seat. Satzinger 3,961,805 (1976) describes seat belts for frontal collisions that provide safety for  
17         vehicles. Such seat belts are in common use. However, they suffer from the drawback that they restrain the body  
18         of the passenger in the narrow regions covered by such belts which may cause injury as other parts of the body  
19         are not restrained. Moreover such belts are not popular, while in common use as the belts are in constant contact  
20         with the body- a factor that is not often relished. Pulling 3,981,520 (1976) describes an arrangement where that  
21         provides passenger movement and protection in frontal impacts. On impact the passenger moves in the vertical  
22         plane of motion to a more protected position while side firing airbags provide frontal protection. This system of  
23         deployment of airbags for frontal collision protection is similar to other frontal airbag systems. They are  
24         necessary as restraining systems during the collision but need to be retracted in conventional passenger  
25         compartments to give passengers access to their seats while mounting and dismounting the vehicle. Erickson  
26         2,777,531 (1957) describes an invention that rotates the seat of the passenger thereby restraining and protecting  
27         the passenger on impact taking advantage of the inertia prior to impact to endow the passenger with rotational  
28         energy that changes the position of the seat. Such rotation can injure the passenger with impacts at present day  
29         passenger vehicle speeds.

30                   All the above items of background art relate to frontal impact protection. None of these  
31         items provide a device that is normally deployed during operation, and provides a broad area of restraint across  
32         the body for the entire upper body, head and neck, without a need for changing the orientation of the passenger.  
33         Moreover none of these items provide any protection for side impacts or provide utility for mounting and  
34         dismounting the vehicle or for the comfort of the passengers in the operating position.

35                   SUMMARY

36                   In view of these prior references what would be useful is an arrangement that diverts the  
37         impact energy in lateral or side impacts away from the passengers to the remaining mass of the vehicle thereby  
38         protecting the passengers, and in the same arrangement provides utilitarian access to the vehicle, such utilitarian  
39         access making it possible to both install multi-element contoured surround seats for passengers and the driver,

1 and also a safety device for head-on collision protection that obviates the need for conventional seat belts and  
2 front impact airbags. Moreover, it would be useful to have a synergistic structural arrangement for the vehicle  
3 that targets strength of the vehicle to protect passengers while minimizing other massive elements in the vehicle.

4 The present invention includes these objects and advantages.

5 OBJECTS & ADVANTAGES

6 Some of the objects and advantages of the present invention are, to provide an  
7 arrangement that diverts the impact energy in lateral or side impacts away from the passengers to the  
8 remaining mass of the vehicle thereby protecting the passengers but decelerating the impacting object  
9 with the remaining mass of the vehicle. Moreover the arrangement synergistically provides a means for  
10 utilitarian easy access to the vehicle for passengers and drivers alike and allows the installation of  
11 multi-element surround contoured seats for the comfort and protection of passengers. This arrangement  
12 differs sharply from the Background art in that it does not simply offer to the impacting body a  
13 reinforced rigid shell where the passenger is treated as part of this integral unit, but rather provides  
14 selective and differential treatment of the mass of the passengers and driver of the vehicle vis-à-vis the  
15 remaining mass of the vehicle. Furthermore the present invention differs sharply from the Background  
16 art in that the resulting structure synergistically permits the installation of contoured multi-element  
17 surround seats and a unique safety harness that protects passengers in head-on collisions, both of which  
18 may not be implementable without the slide or other moving arrangements for seats on either side of the  
19 vehicle in the present invention.

20 Another object and Advantage of the present invention is the gravity slide drive  
21 and a related shock absorbing arrangement relative to the fixed body members of the vehicle ad the  
22 terrain traversed by the vehicle, for my arrangement for which there is no counterpart in the  
23 Background art. This allows further Utility and weight and energy saving in implementing the above  
24 elements of the present invention.

25 Another Object and Advantage of the present invention includes External side  
26 Airbags that differ sharply from the Background art in that for the first time they proactively create a  
27 “Just in Time” deceleration zone both for the passenger relative to the vehicle and also for the vehicle  
28 relative to the impacting body, for the lateral or side impact while not remaining in an extended position  
29 under normal operating conditions of the vehicle.

30 Another Object and advantage of this invention is a perforation resistant shield  
31 for external airbag protection that would reduce the probability of deployment failure. The background  
32 art does not provide for this function in externally deploying airbags.

33 Another object and advantage of the present invention is a indo-skeletal structure  
34 of the vehicle body that permits the energy transfer from the lateral or side impact through compressive  
35 members to the body of the vehicle. Unlike the Background art this indo-skeletal structure is designed  
36 to transfer energy to the body of the vehicle without transferring it to the passengers and driver of the  
37 vehicle. The passengers are targeted for protection with “Safety zones”.

1      **BRIEF DESCRIPTION OF DRAWINGS**

2                  Figure 1 is an illustration of a front elevation of a seating arrangements in a passenger  
3 vehicle. This figure is an illustration of the invention in the normal vehicle operating condition. The impacting  
4 body is represented on the left as still distant but advancing towards the above passenger vehicle.

5                  Figure 2 is an illustration of the same vehicle arrangement as in Figure 1, except that the  
6 impacting object has advanced towards the passenger vehicle adequately to trigger the distance and velocity  
7 sensors.

8                  Figure 3 is an illustration of the same vehicle as in Figures 1 and 2, except that the distance  
9 and velocity sensors have deployed the external Airbags. They may also provide delayed deployment of the  
10 internal Airbags.

11                 Figure 4 is an illustration of the same vehicle as in Figures 1,2 and 3 except that the  
12 impacting object has made impact with deceleration and energy absorption provided by the External airbags and  
13 the shock absorbers and resisted by the mass of the vehicle through compression members as noted below. The  
14 Passengers and seats are free to move away from the impact on the secondary slides as the internal Airbag  
15 deploys, pushing out the Primary slide on the side away from the impact.

16                 Figures 1D, 2D, 3D and 4D illustrate an alternative embodiment with the shock absorbers  
17 mounted internal to the protector shield.

18                 Figures 1C, 2C, 3C and 4C illustrate an alternative embodiment that has an auxiliary beam  
19 mounted behind the seat with a high section of the central member of the skeletal structure behind the seat to  
20 abut the auxiliary beam.

21                 Figures 1B, 2B, 3B and 4B illustrate an alternative embodiment with a center console.

22                 Figures 1F, 2F, 3F and 4F illustrate an alternative embodiment with a center console that is  
23 crushable(an element of “crushable elements” ) and as a result decreases the need for the ejection of the  
24 passenger on the further side of the vehicle at impact.

25                 Figures 1G, 2G, 3G and 4G illustrate an alternative embodiment with center airbags(also  
26 an element of “crushable elements” ) that are a part of a passive airbag system to protect passengers during  
27 lateral impact by absorbing some of the impact energy but more importantly providing a means to inflate head  
28 and neck protection airbags and other anatomical micro cushions mounted in the vicinity of the human body.  
29 This particular embodiment has a crushable center console as well.

30                 Figure 0J and 4 J illustrate: The ejection control – shock absorbing locking mechanisms  
31 (620) that detach for egress and ingress but resistively stretch under lateral impact loads and thereby control  
32 ejection on the far side; Auxiliary brakes (621) for additional control of secondary slide motion under impact;  
33 and the inside airbag deflators (622).

34                 Figure 0K illustrates the alternative structure with secondary slides (111) mounted directly  
35 to the fixed body members (624) and ejecting (625) and non-ejecting (626) elements of the passenger support  
36 mechanisms.

37                 Figure 5 and 6 is an illustration of the seating arrangement as used for loading and  
38 unloading passengers and driver. Figure 5 represents the open position and Figure 6 represents the closed  
39 position.

1 Figures 5A and 6A illustrate an embodiment of the current invention with the protector  
2 shield/shock absorbers/external airbag hinging down to support the primary slide. A useful feature for larger  
3 vehicles with more than a single seat on each side.

4 Figures 7-9 is an illustration of the Gravity slide drive that may be embodied in the  
5 invention. Figure 7 is an illustration of the Gravity Slide drive at the end of the unload cycle for passengers.  
6 Figure 8 is an illustration of the Gravity slide drive at the beginning of the Load cycle for passengers. Figure 9 is  
7 an illustration of the left side loaded and ready for operation of the vehicle and the right side at the start of the  
8 loading operation, emphasizing the independence of the two sides of the Gravity slide drive mechanism.

9 Figure 10 A and B are an illustration of Isometric views of the present invention on one  
10 side of the vehicle for clarity. Figure 10 C is an illustration of a Plan view of the present invention for one side of  
11 the vehicle.

12 Figures 10 A1, 10B1 are isometric views of an alternative embodiment with a vertical  
13 extension/"safety cage" to protect passengers further. Figure 10 C1 is a plan view of the same arrangement.

14  
15 Figure 11. is an illustration of the position of the "Safety Zones" that are targeted for  
16 protection with the Protector shields.

17  
18 Figure 12. A is an illustration of an isometric view of the Seat arrangement. Figures 12B  
19 and 12C is an illustration of the Plan and Side Elevation of the seat arrangement. Figure 12 A1 illustrates an  
20 alternative embodiment of the seat arrangement. Figures 12B1 and 12C1 illustrate the plan and elevation of this  
21 embodiment. Figure 12 D1 illustrates an embodiment of the child seat. Figure 12 E1 illustrates an embodiment  
22 with a different external profile for the seat providing greater protection to the passenger. Figures 12 F2 and 12  
23 G2 illustrate isometric views of an embodiment of the safety harness and 12 H2, 12 I 2, 12 J 2 illustrate an  
24 isometric view of another embodiment of the safety harness, in the normal state, with front impact anatomical  
25 passive micro aircushions deployed, and the head and neck anatomical micro air cushions deployed respectively.

26 Figure 13. is an illustration of a drawing of isometric view of the present invention.

27 Figure 14 illustrates a horizontal cross section of an embodiment of the present invention  
28 at the level of the upper primary slides.

29 Figure 15 illustrates a side impact with internal and external airbags deployed and the  
30 passengers ejected away from the impact.

31 Figure 15B illustrates the deployment of the anatomical passive micro aircushions in a  
32 front impact and the passenger impact protection with the harness and shield. The left side passenger illustrates  
33 the normal position for reference.

34 Figure 15 C illustrates a detailed view of the safety harness and its components.

35 Figure 16A illustrates a passenger ready to leave the vehicle. The safety harness/shield is  
36 still in place.

37 Figure 16A1 illustrates a passenger ready to leave the vehicle. The safety harness/shield is  
38 still in place. Figure illustrates location of Safety Foot switch (623) for operating the egress/ingress ejection  
39 mechanism.

1                   Figure 16B shows the passenger in Figure 16 A after releasing the safety harness/shield  
2 from the locks.

3                   Figure 16C shows the same passenger in 16 A,B but with the safety harness/shield now  
4 well above the head so that the passengers leave the vehicle by simply standing up.

5                   Figure 16D shows the safety harness/shield unlocked from its mounts within the vehicle,  
6 illustrating the flexibility to move within the vehicle under these conditions but not having the visibility to drive,  
7 thereby ensuring that the safety harness/shield is used under driving conditions.

8                   Figures 17 A,B show a schematic diagram of the passive air cushion system disclosed in  
9 this invention.

10                  Figures 18 A-J shows different views of the wheel chair arrangements deployed as  
11 passenger support mechanisms.

12                  Figures 19 A-E show an embodiment of the customizable contoured multi – element  
13 seat.

14                  Figures 20 A-C show an embodiment of the indo skeletal structure that includes special  
15 arrangements for front impact protection and other features for passenger convenience and comfort.

16                  Figures 21 A-F show other alternative embodiments for front impact protection.

#### 10 DETAILED DESCRIPTION OF INVENTION

11                 The present invention provides a passenger vehicle a structure that synergistically  
12 incorporates two functions. First, during lateral or side impacts a means to decouple from impact, and protect  
13 passengers while projecting the remaining mass of the vehicle to decelerate the impacting body, and second,  
14 utility to passengers and drivers, in mounting and dismounting the vehicle with the comfort of contoured  
15 surround seats. The arrangement may in some embodiments use an indo-skeletal beam that allows such  
16 embodiments to rely on compressive force transmission to transfer impact energy to the mass of the vehicle  
17 rather than shear loads that are required in the shell paradigm of construction in most current passenger vehicles.

18                 The present invention may use Primary and Secondary slides on each side of the vehicle,  
19 to meet these objectives. The Primary slide has among other attached devices, a protector shield that bears the  
20 impact force in lateral or side impacts. Such protector shields may be hinged out for access if the sliding  
21 arrangement is not used. The Primary Slide may engage a central indo-skeletal beam in some embodiments. The  
22 Secondary slide is attached among other devices to possibly contoured surround seats (the passenger support  
23 mechanisms). This slide may be activated under impact to guide passengers in their seats away from the impact  
24 zone.

25                 The present invention may utilize a Safety Beam in the vicinity of the seats. However,  
26 there is an important advance over the Background art in that the Beam does not lock the passengers on the path  
27 of the energy transfer, but rather, conducts the energy of impact away from the passenger to the indo-skeletal  
28 frame or to the body members of the shell (collectively elements of the fixed body members) and thereby to the  
29 mass of the vehicle(the massive components of the vehicle such as but not without limitation the motor and  
30 vehicle frame) allowing independent motion of the passengers away from the impact.

31                 The present invention may use proactively fired external airbags which for the first time  
32 provide a means to create a “Just in Time” deceleration zone on the side of a vehicle prior to impact but not  
33 deployed under normal operating conditions of the vehicle. Notably, Background art for external airbags that  
34 are either extended under normal operating conditions of the vehicle or require reactive deployment cannot  
35 function effectively, as the former will impede the maneuverability of the vehicle and the latter will not be able to  
36 create a deceleration zone in time for the impact.

37  
38                 Overall this invention provides a “bottom up” paradigm for the design of vehicles starting  
39 with the human environment and building outwards to the vehicle – in stark contrast to the conventional

1 approach of design that starts with the vehicle and inserts within these constraints, the passenger environment.  
2 Moreover, this invention embodies a two level safety system. The first or the primary level is passive and has a  
3 negligible probability of failure. The second level is active and predictive or proactive, utilizing advanced  
4 technologies. However, complex advanced technology systems have the drawback of higher probabilities of  
5 failure. Therefore while the second level can reduce the level of injury in serious crashes, there is a non trivial  
6 probability of failure of this secondary system. Therefore it is necessary to build a primary system that is good  
7 enough in most cases to reduce injury levels in severe crashes. The paper in the Appendix includes simulation  
8 results for an embodiment of the primary system alone with a failure of the secondary system.

9 The following descriptions are for embodiments of the present invention. Deviations from  
10 this description in an embodiment is possible without deviating from the present invention.

11 **PREFERRED EMBODIMENT**

12 The following is a detailed description of some of the components of this embodiment.  
13 The seating arrangement of a passenger vehicle is shown in Figure 1. The cross section of the central member of  
14 the indo-skeletal structure (101) is fixed to the safety beam lower element (102). The Protector Shield (106) is  
15 firmly attached to the Safety beam Upper element/Upper Primary slide (107), which slides on the Safety beam  
16 lower element/lower Primary slide (102). (The terms upper and lower being used for the slides to distinguish  
17 them and not representing a relative elevation of the slides). The construction of such protector shields would  
18 follow that of any impact resisting body panel member of a vehicle, with the usual weight strength tradeoffs.  
19 Such construction is well disclosed in the background art. The sliding arrangement may use single element or  
20 multiple element direct contact low friction surfaces sliding on one another, roller bearings, ball bearing  
21 structures – all of which are well disclosed in the background art. The Protector Shield(106) are designed to  
22 cover the required “safety zone” (501) as noted on Figure 11. The Safety beam upper element / Upper Primary  
23 Slide (107) locks into the Central member of the indo-skeletal structure (101) in the operating position with  
24 locking devices (112). Such locking devices do not take any additional loads on impact, and may as a result  
25 follow the extensive background art for locking devices for example similar mechanisms to those used in  
26 automobile door locks. These locks may be activated by the ignition key switch for additional safety while the  
27 vehicle is operational. The Protector Shield (106) has attached on the outside a shock absorber (103), which may  
28 include external airbags (104). (the protector shield in this embodiment provides a protective skin on the side of  
29 the vehicle) The construction of such shock absorbers follow the background art. Such external airbag (104) are  
30 protected from sharp objects on impact by a Perforation Shield (105). These perforation shields protect the  
31 external airbag (and the passenger ) from sharp objects. The construction of such perforation resisting shields are  
32 well disclosed in the background art. Such Perforation shields may be attached by conventional means to the  
33 outer surface of the airbag and retained in the normal operating position using techniques used for airbags both  
34 internal and external disclosed in the background art. The Air Bag (104) is deployed with distance and velocity  
35 sensors (113) mounted on the Perforation shields (105). Distance and velocity sensors are used in other  
36 applications and their construction is well disclosed in the background art. The Safety beam upper  
37 element/Upper Primary Slide (107), supports the secondary slide/Impact decouplers (111). In this embodiment  
38 this is firmly attached to the Safety Beam Upper element/Upper Primary Slide until the impact when it is  
39 decoupled to slide away from the impact. The Secondary slide arrangement may use a friction based approach,

1 or other approach , all of which are well disclosed in the background art. This embodiment has contoured  
2 surround Passenger Seats (109) that are mounted on the Secondary slides (111). These seats have internal  
3 Airbags (114) that deploy on impact and may "unfurl" upwards to protect the head or upper body as well. The  
4 construction of seat adjustment mechanisms are well disclosed in the background art. This Figure shows the  
5 impacting object on the left approaching the vehicle, but too distant to trigger any action.

6 In Figure 2, the impacting object has moved to a position that can now trigger the distance  
7 and velocity sensors (113). These sensors trigger the deployment of the External Airbags (104), and the shock  
8 absorbers (103). The internal airbags (114) may be triggered by conventional means disclosed in the prior art,  
9 explicitly or implicitly reacting to proactive or reactive impact detection. The internal air bags are designed to  
10 move the passengers and the passenger seats to the extent necessary through a Motion Space to a Safe Position  
11 on primary impact detection, and thereafter protect the protected entity – the passenger and the seat. Thereafter  
12 as illustrated in Figure 3, the External Airbags (104) and shock absorbers (103) deploy to provide the required  
13 deceleration zone for the impact. As a result on impact the energy of impact is partially absorbed by the External  
14 Air bag (104) and the Shock Absorber (103) and the remaining energy transferred to the massive components of  
15 the vehicle through the Protector Shield (106), the Safety beam upper element/upper primary slide (107) and the  
16 safety beam lower element/lower primary slide (102) to the Central element of the Indo-skeletal frame (101) and  
17 the body of the vehicle. Notably, the Secondary slides (111) decouple and slide the passenger seats (109) with  
18 the passengers away outside the path of the impact forces and protected by the internal Airbag (114). The Safety  
19 beam upper element/ Upper Primary Slide (107) on the side of the vehicle away from the impact is free to slide  
20 out with all devices mounted on it to provide a path for the secondary slide (111) and the seats (109). In this  
21 situation it may be seen that the Safety beam upper element/upper primary slide works as an impact-resisting  
22 beam on the side of the impact and a release and support mechanism on the side away from the impact. Figure  
23 15 A illustrates the side impact with the deployed internal and external airbags, and the displaced passengers  
24 away from the impact in the vehicle sustaining the lateral impact. Figure 15 B illustrates the frontal impact  
25 support for the passenger on the right hand side. The Left hand passenger is shown in the normal position for  
26 comparison.

27  
28 Figure 14 illustrates a horizontal cross section of the embodiment at the height of the safety  
29 beam upper element/upper primary slides (107). The central member of the indo-skeletal structure (101) is  
30 flanked by the safety beam upper element/upper primary slides (107) abutting the central member, with the  
31 protector shields (106) and the shock absorbers that include the external airbags (103,104) at the outer end of the  
32 safety beam upper element/upper primary slides. The perforation shields are shown at the outer extreme of the  
33 shock absorbers and airbags. In this embodiment there are two sets of safety beam upper element/upper primary  
34 slides on each side of the vehicle that can support two rows of seats (front and rear) one on each side with its  
35 own protection with the protection shields and shock absorbing devices.

36  
37 An auxiliary slide beam structure (108) (as illustrated in figures 10A, 10B and 10C) may  
38 be attached to the central member of the Indo-skeletal beam (101) and locked into the protector shield when the  
39 vehicle is ready for operation, or be attached to the protector shield and slide out with the Safety beam upper

1 element/upper primary slide (107), and get locked to the central member of the Indo-skeletal structure (101) in  
2 the operating position

3 Means for access for passengers in this embodiment as illustrated in Figures 5, 6, 10A,  
4 10B and 10C. The seat (109) and secondary slide (111), slide out on the upper Primary Slide (107) to a position  
5 that lets the seat (109) protrude from the vehicle such that the passenger may simply stand in front of the seat  
6 and sit down on the seat (109). Thereafter the seat (109) is retracted on the Primary slide to the position as  
7 depicted in Figure 6, where the Safety beam upper element/upper primary slide (107) is locked with the locking  
8 devices (112) in position for operation of the vehicle. The slide drive mechanism may be powered using  
9 approaches well disclosed in the background art such as servos, and pneumatic or hydraulic systems. The vehicle  
10 while in operation should have the Upper Primary Slide (107) retracted and locked. The ignition lock is used in  
11 this embodiment to ensure this practice.

12 While extended, the clearance on the side of the vehicle for the Easy Ejector will usually  
13 be in the range of about 20 inches to 30 inches. This could be substantially less than the clearance required for  
14 opening a conventional car door. This is particularly useful for parking in areas with limited clearance.

15 Figures 12A, 12B and 12C illustrates the detail of the seat (109). The seat (109) may be  
16 constructed with customizable multi-elements that conform to the desired shape and provide the desired support  
17 for the passenger. Such adjustments may be effected using conventional seat control devices. In this figure the  
18 Safety Harness (119) is secured to the sides of the contoured seat (109) between the arm rests (122). The safety  
19 harness (119) may be designed to protect the passenger in head-on collisions by providing a soft barrier in close  
20 proximity to the body but not necessarily touching the body. This arrangement may be preferred to seat belts  
21 that do not provide the extended surface area that the harness (119) provides and as result provides greater  
22 impact resistance for the same level of limiting forces that the body can withstand. Moreover, this arrangement  
23 may obviate the need for a front collision airbag as the harness (119) may be high enough to support the face  
24 and neck under collision conditions. The harness may be constructed of pliable but semi-rigid material (such as  
25 high strength nylon) to provide support in a head on collision. A natural benefit of the arrangement of the harness  
26 (119) and its supports (120) is that lateral forces on the seat are also braced by the harness support (120) in the  
27 operating position. Figures 12 F 2 and 12 G2 illustrate an embodiment of the harness. Moreover the seat (109)  
28 may be constructed with reinforcing on the sides to further protect the passenger from crush injuries. The  
29 Seating surface (121) is illustrated in the same figure as are the arm rests (122). In conventional vehicle seat  
30 designs the door surface provides the only support on the external side surface which are usually limited to arm  
31 rests. This seat (109) provides surround support for the passenger particularly desirable on winding roads. The  
32 “Custom contoured seats” customized for each passenger may be created with a multi-element adjustable  
33 structure (the customized multi-elements) – manually with inserts or with computer controlled elements- that  
34 provide ergonomic passenger comfort providing where desired, lateral support in addition to the support that  
35 conventional seats provide, to cradle the entire lower body in the ejector seat. Similarly child seats (123) as in  
36 Figure 12D1, may be designed to protect children. Such seats can be inserted into the seat (109). The Safety  
37 harness may also have an attachment for providing greater support for infants and small children.

1           ADDITIONAL EMBODIMENTS

2           While the above embodiment uses a power slide drive, this embodiment differs in that a  
3       gravity slide drive is employed to move the slides for mounting the vehicle. Figures 7,8 and 9 describe this  
4       arrangement. This embodiment differs in the preferred embodiment above in that the Safety Beam Lower  
5       element/Lower Primary slide (102) are pivoted at the Central member of the indo-skeletal structure with pivots  
6       (118). As shown in Figure 7, this allows the lower slide to fall to a lower of two positions, that inclines the upper  
7       surface of the Safety Beam Lower Element/Lower Primary slide (102) adequately to allow the safety beam upper  
8       element/upper primary slide (107) to slide outwards to the loading position assisted by the weight of a passenger  
9       in the seat and the additional assistance of the Spring arrangement (115). The passenger may dismount from the  
10      vehicle when the slide is fully extended as shown in Figure 7. Each side of the vehicle has independent slides and  
11      may be operated by passengers independently.

12          When the passenger dismounts from the seat the Safety beam upper element/upper primary  
13       slide (107) in its extended position moves to the higher of two positions about the Pivot (118) as illustrated in  
14       Figure 8. This move inclines the Upper surface of the Safety Beam Lower Element/Lower Primary slide  
15       adequately to allow the weight of a passenger to work against the spring arrangement (115) and move the slide to  
16       the operating position. This move up of the Safety Beam Lower Element/Lower Primary Slide (102) may be  
17       effected by mechanisms well disclosed in the background art. The Slide as depicted in Figure 8, is now ready for  
18       a new Passengers to mount. When the passenger sits on the seat (109), the weight of the passenger works against  
19       the spring mechanism (115) to move the slide to the operating position as depicted on the left hand side of the  
20       figure 9 and lock the slide in the operating position. The Safety beam upper element/upper primary slide may be  
21       unlocked by the passenger by depressing the Inside Door Open Button (116). Activating this button in addition  
22       allows the Safety Beam Lower Element/ lower primary slide (102) to move and be locked to the loading  
23       inclination - the lower of two positions, and the Safety beam upper element/upper primary slide (107) is free to  
24       slide out with the passenger. At this point the arrangement has completed a full cycle and is in the position  
25       depicted in Figure 7.

26          The above cycle represents operation of the Gravity Slide Drive when there is a passenger  
27       in the seat (109) when the Slide moves to and from the operating position as on the left of Figure 9. When a passenger  
28       dismounts however, and the Slide arrangement needs to be retracted without a passenger in the seat,  
29       the weight of the passenger is no longer available for aiding the motion of the slide to the operating position, and  
30       the slide must be pushed in against the action of the Spring Arrangement (115) and locked in place at the  
31       operating position. When a new Passenger wishes to mount the vehicle, he/she will press the Outside Door Open  
32       Button (117) which releases the catch that holds the Safety beam upper element/upper primary slide beam in  
33       place but does not affect the movement of the Safety Beam Lower Element/Lower Primary Slide (102) about its  
34       pivot (118). The seat as a result slides out on the Safety beam upper element/upper primary slide assisted by the  
35       Spring arrangement (115) to the position for mounting the vehicle as depicted in Figure 7. The spring  
36       arrangement (115) is designed to be such that it provides a force just adequate to move the Safety beam upper  
37       element/upper primary slide out with no passenger in the seat.

38          Some alternative embodiments may have multiple positions for the inclinations of the  
39       safety beams from the center of the vehicle, in the loading position to accommodate the varying road inclinations

1 that may make a single inclination of the safety beam in the loading position inadequate. In such an embodiment  
2 the operator will have the facility to switch to the best loading inclination dependant on the inclination of the  
3 road. This will overcome some of the disadvantages of regular car doors on steep hills. Moreover, this  
4 arrangement can also function as a shock absorbing device for the comfort of the passengers in vehicles under  
5 operating conditions. A possible embodiment to achieve this can have a range of angular inclinations for the  
6 operating position, the range being set so that the transfer of the compressive load on impact through to the fixed  
7 body members of the vehicle or the central beam is achieved. The Safety beams are spring or shock absorber  
8 mounted in a vertical plane relative to the central beam and the fixed body members of the vehicle. When a  
9 bump in the road is encountered the safety beams pivot on the center and swing higher at the center thereby  
10 isolating the passenger from the road.

11 Some embodiments of the multi-element contoured seats may have a structure that  
12 provides anatomically accurate support for the body as illustrated in Figures 19 A,B,C,D and E. This seat  
13 architecture may be used in a wide variety of applications outside vehicles as well. Conventional car seats are a  
14 set of two or possibly three rigid structures - the seat bottom, the back and the head rest. These have some  
15 mobility for comfort. However there are two factors that militate against their comfort and the level of protective  
16 support they can provide in collision situations. First, one size must fit all passengers and drivers. The mobility  
17 provided for the seat bottom, seat back and head rest provide limited flexibility for passengers of different sizes.  
18 Second, there is little lateral support for the body that could be vital in a side collision, and third, in a vehicle in  
19 motion on a rough surface, the shock absorption provided to all parts of the upper body is the same. – the seat  
20 back is rigid once set up by the passenger – this stands in contrast with the internal shock absorption of the  
21 human body, where the spine provides differential shock absorption to different parts of the body, increasing the  
22 shock absorption towards the head. This last factor implies that conventional seat backs cannot remove  
23 vibrations from both the top and the bottom of the upper body as the body's own shock absorption system will  
24 move differentially to the seat back along the length of the spine. The embodiments of this invention illustrated  
25 in figures 19, improve these characteristics of seats.

26 Figures 19 A and B show two views of a shadow vertebra of the seat. The design of this  
27 vertebra is to provide auxiliary support for the body. The structure shown is one of several possible structures  
28 for embodiments of this invention. The body of the vertebra in this embodiment is split into a left body (164 )  
29 and a right body (165) these elements are permanently bonded or fixed together by bolts. The body has two  
30 cavities on each of the top and the bottom surface – the air cell sockets. These hold two air cells on the left and  
31 the right side. These air cells are supported on the sides by the air cell retainers (159) that slide in and out of the  
32 air cell sockets (166, 167, 171, 172). The air cells themselves are made of a pliable and inflatable material, or  
33 alternatively a material that can fold within the cell supports. Each pair of air cells are separately inflatable by a  
34 multi channel air pump that is installed in the seat embodiment. There is a connecting tube between the left and  
35 the right air cells housed in the lateral tilt air cell visco-elastic damper tube. This tube allows limited air flow  
36 between the left and the right chambers to permit lateral tilting of the vertebrae relative to each other. This  
37 motion however is corrected by the lateral tilt return spring (160) that ensures that in the normal position the  
38 vertebrae realigned vertically. This lateral tilt return spring is fixed on one end to a vertebra in the upper fixed  
39 slot for lateral tilt return spring (161) and can slide within the next vertebra in the lower sliding slot for lateral tilt

1 return spring (174). Orthogonal support is provided between the vertebrae with the support flange (162) that is  
2 fixed at one end in the lower slot for the support flange (173) and is slidably mounted in the adjoining vertebra's  
3 upper slot for support flange (163). The flange is sized to allow limited lateral tilting as the vertebra tilts laterally,  
4 but provides firm back support. Notably the upper and lower slots for the support flange may be inclined slightly  
5 so as to take the form of the human spine. The body contact is made on the back with the back support adjustable  
6 air cushions (170), which in most embodiments are contoured to the shape of the body and is illustrated as an  
7 ellipsoid for clarity. These air cushions are inflatable and the pressure may be adjusted to the comfort of the  
8 passenger. There may be a spring loaded cable that is threaded through the vertebrae to tie them together. The  
9 spring loading will work against the air cell pressure as the gets elongated with higher air cell pressure. Ideally  
10 there can be as many of the shadow vertebrae as vertebrae in the human body although some embodiments may  
11 choose some economy in the number of such shadow vertebrae. Figure 19C illustrates two adjoining shadow  
12 vertebrae. One of these are for supporting the thorax region and therefore have attached the shadow rib body  
13 (175) and the related shadow rib adjustable air cushions (176) (shown as ellipsoids for clarity but in most  
14 embodiments will be contoured to take the shape of the body. These air cushions are inflatable for passenger  
15 comfort. The air supply being led to the cushions along the rib body and down the shadow spine to the multiple  
16 channel control air pump which also supplies air pressure of each of the many air cushions and air cells in the  
17 seat embodiment. The shadow ribs are supported by the tilt control connectors(177) that may adjust the angle of  
18 the shadow ribs. Figures 19 D and E .illustrate one possible version of this embodiment. Here the shadow  
19 vertebrae are stacked up to provide support for the head the neck the shoulders, the thorax and the lumbar region.  
20 The head rear support adjustable air cushions (183) provide forward support for the head while the Head lateral  
21 support arms with deploying passive air bag (182) provides lateral support particularly during side collisions  
22 with deploying passive micro airbags. Similarly the neck has rear support from neck rear support adjustable air  
23 cushions (184) and lateral support from Neck lateral support with deploying passive micro air bag (181). The  
24 shoulders are supported by the shoulder bolster (178) and the shoulder bolster adjustable cushions (179). The  
25 shoulder bolster being pivotally attached to a vertebra of the shadow spine and allowed limited pivotal motion  
26 vertically to allow the passenger to move his/her upper arms upwards at normal speed. However, the shoulder  
27 bolster will resist rapid motion of the upper arms and shoulders as in a collision thereby supporting the  
28 passenger. This differential movement characteristics can be achieved by approaches well disclosed in the  
29 background including viscous loading of the coupling. Lumbar support is provided by the Lumbar support  
30 adjustable air cushions (185). The entire array of the shadow vertebrae may be elongated and contracted by  
31 changing the pressure in the air cells thereby providing the optimal sizing for all heights of passengers. The  
32 lateral support and back support cushions may be inflated to provide width control and support for passengers of  
33 different shapes. Adjustable hip bolsters provide lateral and forward support while the adjustable pelvic support  
34 (187) provides vertical support for the passenger. The illustrations exclude the leg and arm supports that are part  
35 of the embodiment for sake of clarity. Spring supports can substitute for the air cells in the vertebrae but will not  
36 have the advantage of viscous lateral resistance and independent height control. Overall height can however be  
37 controlled with the cable threaded through the vertebrae. Motion control of the seat elements can be achieved  
38 with devices well disclosed in the background art including servos, and pneumatic and hydraulic systems.

1 Considering the complexity of the seat systems including the multi channel inflators for  
2 each of the air cells and the air cushions along with the mechanical controls for inclining the shadow ribs and the  
3 pelvic and hip supports, it would normally be necessary to use a closed loop feedback with computer control.  
4 Pressure sensing of each air filled device will provide feedback on the resistant force o the human body and  
5 therefore firmness of the support. This information can be used to provide the firmness control desired by the  
6 passenger. One computer controlled scheme could be where the passenger inputs gender weight, and height and  
7 the computer alters the size of the seat by inflating and deflating air cells and cushions accordingly and the  
8 provides several alternative configurations that the customer can select. The customer can then customize  
9 firmness and variations on the seat presets.

10 Finally the shoulder bolsters and shadow ribs may have deploying micro aircushions that  
11 hold the passenger in the event of a collision.

12 Yet another variation of this embodiment discharges the air in the adjustable air cushions  
13 when passengers leave the seats, and then reinflate these aircushions when the new passenger sits down with air  
14 that is preheated or precooled to the preferred temperature of the passenger. Thereafter the air cushions will  
15 provide insulation at that temperature for the seating surface.

16 Embodiments, particularly those that utilize the indo-skeletal structure may include the  
17 following additional embodiments and variations thereof as support arrangements for a passenger environment  
18 and for frontal and rear impact protection in a safe passenger environment and passenger comfort and  
19 convenience. The additional structure is illustrated in figures 20 A,B and C. The passenger support platform  
20 (198)represents the set of machinery for that purpose. It will take the shape needed to support the variety of  
21 structures that are described in this invention. It is supported either in the middle or on the edges by the Central  
22 body tubes (188) said support being on attachment surfaces of said central body tubes. The first tube that fits into  
23 the central body tube is the Body extender tube (189) This optional tube is slidably connected to the central body  
24 tube and may be moved in and out by servo motors or pneumatic/hydraulic pistons and cylinders (the “first  
25 motion control elements”). However the inner tube is axially supported by a compression resistant shock  
26 absorber (the “first shock absorbing elements”) which in turn is mounted rigidly with regard to the outer central  
27 body tube in all positions that the body extender tube can take. The Body extender tube (189) has functions that  
28 include extending the wheel base of the vehicle under computer control particularly in drive by wire vehicles,  
29 thereby improving the comfort of the vehicle and second increasing the wheel base contingent on vehicle speed  
30 such that in the event of a collision there is a longer deceleration space. The shock absorber will become longer  
31 and shorter to accommodate this need and can for example be air shock absorbers. The correlation of speed and  
32 length will normally be computer controlled to provide statistically appropriate deceleration distances for the  
33 speed of the vehicle at any time. Notably the steering arrangements and other vehicle systems may also need to  
34 be compensated to accommodate the change in wheel base to ensure driver convenience and precise control of  
35 the vehicle. The Front end connector tube (190) has a shock absorber (the “second shock absorbing elements”)  
36 in series with a servo or pneumatic/hydraulic controlled actuator (the “second motion control elements”) for  
37 axial movement in and out of the body extender tube (189) as does the back end connector tube (191). 190 and

1 191 are connected to the front and back ends respectively (192,193) which include the front and back wheels.  
2 and bumper arrangements. The front module (194) – which may be the engine or hybrid unit is pivoted on  
3 brackets at the front end of the front end connector tube, thereby allowing the module to rotate upwards about  
4 this pivot. Notably the modules (194, 195) will be significantly massive and will require strong supports and  
5 pivots. The front module crank (196) is pivotally attached to the body extender tube and also pivotally attached  
6 to the front module as shown in figure 20 A. Similarly the rear module crank (197) moves the rear module.  
7 Therefore if there is a movement of the front end towards the body extender tube the front module crank would  
8 swing the front module about its pivot in the front towards the vertical direction.

9 There are at least two functions for this motion. First in the event of a front collision the  
10 force will compress the shock absorbers on the end of the front end connector tube and thereby force the crank to  
11 pivot up the front module. This angular acceleration of the massive front module (massive element) will absorb  
12 energy of the impact and acting as a “fly wheel”, remove acceleration spikes that the passenger would otherwise  
13 sustain and in addition due to its vertical acceleration increase the traction on the front wheels thereby increasing  
14 the braking friction resistance that can be offered because of an increased force on support surfaces. In addition  
15 the kinetic energy of the impacting object will be converted to heat energy in compressing the shock absorbers.  
16 Finally in the event of a collision the inclining front module will divert the impacting vehicle over the passenger  
17 space. This action is illustrated in figure 20 C. Second, particularly for drive by wire vehicles, the front and back  
18 end connector tubes may be retracted by servo or pneumatic/hydraulic arrangements, to pivot up the front and  
19 back modules thereby reducing the vehicle length substantially and providing better curb visibility to the driver  
20 particularly while parking. This is illustrated in Figure 20 B. Notably the wheels are maintained in the same  
21 orientation to the road surface and may be steered as desired with the same mechanisms. For conventional  
22 vehicle architectures the pivot of the front module and engine with the front end connector tube should be near  
23 the wheel axis to facilitate this additional feature.

24 The same value is derived in the rear structure as the front structure for rear collisions and  
25 in front collisions and in parking. The arguments are similar.

26  
27 Another embodiment may have a single but broad set of central body tube body extender  
28 tube and the back/front end connector tubes with a split front or back module and connection of the front / back  
29 connector tube with the front /back ends respectively in the middle. Yet another configuration may have a single  
30 central body tube and body extender tube but then have a “T” shaped structure on the back or the front to have  
31 separate left and right front and/or back end connector tubes connected with the front end at either side. In the  
32 event the body extender tube is not used the connection of the front/back module cranks will be to the central  
33 body tubes.

34 For embodiments that use an exoskeletal or shell design, an additional embodiment  
35 deploys airbags in the space surrounding the engine components to change the characteristics of the crumple  
36 zone. Moreover in addition some of these embodiments have the passenger cabin slidably and detachably  
37 connected to the rest of the vehicle and mounted behind these deploying airbags such that on impact, the cabin  
38 detaches from the vehicle and slides backwards in a controlled fashion to ensure the integrity of the cabin.

1  
2       ALTERNATIVE EMBODIMENTS

3           In an alternative embodiment to the preferred embodiment, the present invention may use  
4       hinged Protector Shields (106) that lock into the Primary Slide (107) when closed. This will allow the  
5       arrangement to work for mounting and dismounting the vehicle with either the Primary Slides deactivated or  
6       non-operational as well as when they are functional. The seats may also be mounted on rotating mechanisms  
7       or extension arms rather than a primary slide, to assist passengers in mounting and dismounting.

8  
9           Another alternative embodiment utilizes co-axial sliding mechanisms that constitute said  
10      rotating mechanisms rather than the primary slides such that the fixed and rotating members of said rotating  
11      mechanisms have an adequate area of contact and reaction to support lateral collision forces.

12  
13          Another alternative embodiment is illustrated in Figures 5A and 6A. The “door” that  
14       contains the perforation shield (105) with distance/velocity sensors (113), the external airbags (104), the shock  
15       absorbers (103) and the protector shields (106), hinges down on the pivot (112A) to provide support for the  
16       safety beam upper element/upper primary slide. The inner surface of the Protector shield is designed to perform  
17       the function of the Safety Beam Lower Element/lower Primary slide (102). This embodiment will be particularly  
18       useful for larger vehicles with a plurality of seats on each side of the vehicle. These multiple seats may be  
19       mounted on separate sections of upper primary and secondary slides.

20          Another alternative embodiment is illustrated in figures 1D to 4D where the Shock  
21       Absorbers (103) excluding the External Air bags (104) are mounted on the inner surface of the protector shields  
22       (106). As may be seen from the drawings, in this particular embodiment, the shock absorber excluding the  
23       external air bags are locked directly to the Safety Beam Lower Element/ lower primary slide (102) in the  
24       operating position, although in another configuration the locks may be between the protector shield and the lower  
25       primary slide in the operating position. Such embodiments may be designed to allow limited intrusion of the  
26       protector shield with resistance provided by the shock absorber (103) thereby reducing the peak acceleration  
27       sustained by the vehicle body under impact. Notably, as the passenger environment is protected and moves away  
28       from the impact, crush injury to the passenger is avoided. This is a unique feature of this invention where both  
29       the crush injury of the passenger and the peak acceleration of the vehicle (and the passenger as a result) may be  
30       minimized at the same time. Conventional designs try to minimize intrusion by bracing the side of the vehicle  
31       with beams and thereby increasing the peak acceleration of the vehicle, or increasing intrusion to reduce the peak  
32       acceleration but allowing greater crush injury.

33          Another alternative embodiment may have a contoured safety harness with a different  
34       shape to that of the preferred embodiment. Figures 12 A 1 to 12 C1 illustrate an embodiment of a safety harness  
35       using a slightly different geometry but performing the same function in the same way as in the preferred  
36       embodiment.

37          Some embodiments of the multi-element contoured seat may have sides that fold down and  
38       away from the passenger. This feature is useful for the inner side of the passengers near the side of the vehicle  
39       and for both sides of the passengers in the middle of the vehicle, if the center seats are fixed and not ejectable.

1 Notably however, the sides lock in the operating position and brace the seat from lateral compression, thereby  
2 protecting the passenger.

3 Some embodiments of the seats may have sides that could include arm rests, side bolsters  
4 and other elements as disclosed in this invention, that drop down or back on the door or access side at the  
5 time of egress and ingress, particularly in embodiments that use conventional doors for access. Activation for  
6 these movements can be with the switching on and off of the ignition switch for the vehicle.  
7

8 Yet another embodiment raises the seat bottom at the time of egress and ingress with servos  
9 or pneumatic/hydraulic systems, so that the seat members on the sides of the sat are relatively lower to the seat  
10 bottom thereby facilitating egress and ingress of the passenger. . Moreover, arrangements to raise the seat  
11 bottom may in addition in some embodiments help negotiate a high “door” sill by the sliding or rotating seats at  
12 egress and ingress.

13 Yet another embodiment using conventional doors, has the arm rests on the door side  
14 integrated in to the doors but protected and decoupled from the door members on its outside by inside air bags.  
15 This design would have these arm rests locking into the seat when the door is closed thereby providing the  
16 decoupling for the entire seat with the inside airbag during lateral impact.

17 Another alternative embodiment uses shock absorbing devices mounted at each end on  
18 each of the two surfaces of the impact decoupler/secondary slide substituting or supplementing the inside  
19 airbags.

20 Another alternative embodiment may have an auxiliary slide behind the seat and of any  
21 convenient height. This embodiment is shown in figures 1C -4 C. The figures illustrate the working of the current  
22 invention with a high section of the central member of the indo skeletal structure behind the seats, but abutting  
23 the auxiliary beams in the operating position. As the High section of the central member (101) is behind the  
24 seats and the secondary slides (111), the seats and the secondary slides are free to move across the vehicle under  
25 impact as shown in figure 4 C.

26 Yet another alternative embodiment has an external seat profile as illustrated in figure 12 E  
27 1. The higher rectangular external profile provides greater protection to the passenger.

28 Yet another alternative embodiment has a vertical extension/ “safety cage” (125) as shown  
29 in figure 10 A1, 10B1 and 10C1. Here the vertical extension/safety cage engages a beam across the top of the  
30 vehicle that may be supported by the shell structure of the vehicle (the figure shows only half the width of the  
31 vehicle). Such a safety cage/vertical extension can provide protection in a roll over situation and also provide  
32 additional compressive strength for the vehicle, and may function as a fixed or retractable roll bar. In some  
33 embodiments such a vertical extension “safety cage” will perform the function of the “B” pillar of the vehicle  
34 under lateral impact. Notably no “B” pillar is needed to support rear door hinges in the present invention.  
35 Moreover, in some embodiments the beam arrangement across the top of the vehicle or other support structures  
36 on the roof section of the shell may be designed to be rigid on compression but telescope out with the secondary  
37 slides under impact using appropriate logic to drive the locking mechanisms, thereby providing a protective cage  
38 even when the seat is in the ejected state.

1 Yet another embodiment, deters a roll over following side impact, by implementing an  
2 “outrigger” arrangement having reinforced safety beam upper element/upper primary slides and/or secondary  
3 slides and bracing brackets anchored to the fixed members of the vehicle that hold these slides in their extended  
4 substantially horizontal position after extension under impact, without permitting them to buckle under vertical  
5 forces encountered under the initial stage of a roll over situation.

6 The preferred embodiment has the external airbags or shock absorbers triggered on  
7 detection of an expected impact as noted. This implies that on the far side (non-impact side) if there is possible  
8 secondary impact from a second object, the same mechanisms will deploy the external airbags on the second  
9 side, thereby protecting the far side occupant in the event of a second object hitting the vehicle soon after the  
10 first. An alternative embodiment can have distance/velocity sensors mounted in positions on the front and back  
11 edge of the perforation shields or protector shields to facilitate better detection of objects approaching the  
12 vehicle at wide angles to the perpendicular direction. Yet another alternative embodiment to this will have both  
13 impact side and far side external airbags deploy on detection of the first impact.

14 Another alternative embodiment has a safety harness/shield as illustrated in Figure 12H2.  
15 This embodiment of the safety harness is mounted on spring loaded hinged supports (137) at the head support  
16 section of the multi element adjustable seat - similar to conventional supports for the headrest, and to lockable  
17 supports (138) between the arm rests or on the side bolsters of the multi element adjustable seat. The spring  
18 loading will support the weight of the harness and thereby retract the harness when unlocked. The harness  
19 includes a hinged and spring mounted shield (130) that may pivot on the lower safety harness support (138). The  
20 passenger side of the shield, has on its surface an implementation of a Passive Air Cushion System that uses the  
21 pressure in one or more sacrificial chambers which under pressure transfer air to one or more micro-air cushions  
22 that protect high priority anatomical regions. In this embodiment, the passive anatomical micro air cushion  
23 (131), derives its inflation source from the sacrificial chamber (139) at the lower end of the shield of the safety  
24 harness, that is compressed by a much greater body mass under impact. In a frontal collision the force of the  
25 more massive parts of the body on the sacrificial chamber will deploy the passive anatomical micro-air cushions  
26 to protect the face and the neck. The narrower sections of the aircushions and flow control mechanisms if  
27 installed, will cause some visco-elastic behavior and in addition cause air speed amplification to create faster  
28 deployment. While this mechanism activates the shield (130) may pivot down to take some of the impact energy.  
29 The shield is shaped to the contour of the human body head and neck when it is forced forward as in a frontal  
30 collision. This embodiment may in addition have multiple or variable position harness support anchor points on  
31 the arm rests or the side bolsters that are part of the multi-element seat, to accommodate people of different  
32 proportions. Moreover this embodiment may have in addition an additional bracket that moves the anchor point  
33 of the lower safety harness locking supports substantially forward, and provides a supplementary passive  
34 anatomical micro-air-cushion that can be mounted on the permanent micro-air-cushion on the shield, to  
35 accommodate pregnant women, and the special critical force distribution they can withstand.

36 In this embodiment, the two pivoted arms swing forward under collision forces the  
37 moment created by the shield with the body pressure against it, and extends the upper extending arms (133) to  
38 absorb some of the shock and to provide a space for the forward movement of the upper body. The elbows (132)  
39 facilitate the relative angular movement of the upper arms and lower arms of the safety harness (133,134). They

1 are spring loaded to ensure that they support the lower parts of the harness when unlocked to allow the entire  
2 harness to move up and away from the body when unlocked without any force being applied. Under side impact  
3 the passive anatomical head and neck micro-air-cushions deploy to protect the head and neck under relative  
4 lateral acceleration. Notably the passive anatomical head and neck micro-air-cushions can be actively deployed  
5 or as in this embodiment passively deployed by a discharge of air from sacrificial chambers between the seats or  
6 on the outer surface of the seats and mounted on each of the seats, so that lateral pressure will inflate the  
7 anatomical head and neck micro-air-cushions. The sacrificial chambers offer secondary impact protection by  
8 cushioning the seat. Notably this embodiment does not use any active airbags in the vicinity of the human body,  
9 reducing the risks associated with the high energy external deployment devices. The adjustable head rest (136)  
10 follows conventional design but is here mounted on the safety harness hinged mounts.

11         Figure 12 I 2 shows the passive anatomical micro-air-cushions deployed (the sacrificial  
12 chamber has been compressed and the top region is full and ready to protect the face and neck in a frontal  
13 impact. Figure 12 J 2 shows the anatomical head and neck passive micro aircushions deployed under side  
14 impact, ready to support the head and neck in a side collision. Notably this embodiment uses a new concept  
15 where the impact energy is redeployed for protecting vital parts of the impacted object which are often  
16 embedded inside the object, using fluid transfer – in this case air transfer. Force and velocity amplification or  
17 deamplification can be achieved with the geometry of the interconnections, the sacrificial chambers and the  
18 micro-air-cushions. The sacrificial chambers can be used for secondary impact protection as well by carefully  
19 controlling the flow parameters. This is illustrated in Figure 17. The approach obviates the need for active  
20 airbag technologies in the vicinity of sensitive equipment, living organisms and indeed people.

21         This embodiment of the harness allows movement within the vehicle for passengers when  
22 it is unlocked and allowed to swing up within the vehicle as shown in Figure 16D. However, visibility is  
23 somewhat obstructed preventing the driver from driving without locking the harness in place.

24         In this embodiment of the safety harness entering and leaving the vehicle are facilitated by  
25 the entire device swinging away from the body as shown in Figures 16 A,B and C. The passenger simply needs  
26 to stand up to leave. To enter the passenger simply sit down and place his/her feet on the foot rest (141) and  
27 retract the slider mechanism. This embodiment also has radar or infrared detectors as on elevator doors to detect  
28 limbs in the way of the retracting sliding mechanism for the protection of the passengers.

29         Figure 15C shows the parts of this embodiment and the adjustable arm rests.

30         Another embodiment of the shield on the safety harness has a folding section at the top that  
31 can be straightened and locked in place for adults and folded down for children.

32         Another embodiment uses flexible netting on part of the shield surface to protect  
33 passengers under impact. In this embodiment, the shield has a frame on which the netting is deployed. The  
34 upper end of the frame is adequately bent forward and then downwards to ensure that the passenger head and  
35 neck do not strike the frame under frontal collision. In yet another embodiment of this arrangement, the shield of  
36 flexible netting is designed for the head and neck and is normally retracted forward, and deployed on impact by  
37 initial forces by the lower torso of the passenger against the lower part of the safety harness/shield.

1 Yet another variation of this safety harness with netting on a frame, has telescoping frame  
2 members on the sides so that the height of the frame is adjustable by retraction of the telescoping members to  
3 accommodate children and small adults.

4 Yet another embodiment of the harness has an upper section of the safety harness  
5 consisting of spring mounted support arms mounted in the vicinity of the head rest and designed --when pulled  
6 down by the passenger --to swing down and over the passenger head and in front of the passenger. The support  
7 arms each having telescoping sections that connect to the shield, such telescoping sections having arrangements  
8 for an inertial ratcheting that prevent extension of these telescoping arms in the event of a sudden tension as in an  
9 impact. The lower section of the harness consists of short adjustable belts or arms that can be locked on the sides  
10 of the seat or on the inside of the arm rests as in a four point seat belt. This embodiment provides all the benefits  
11 of a four point seat belt but in addition has the benefit of head and neck support in the event of a collision. This  
12 arrangement allows protection with the telescoping sections and the adjustments on the lower end of the harness  
13 for different sized passengers.

14  
15 Yet another embodiment utilizes the passive anatomical micro air cushion (131) at the top  
16 of the shield/harness that derives its inflation source from the sacrificial chamber (139) at the lower end of the  
17 safety shield/ harness. However, in this embodiment the anatomical micro air cushion is limited to only the top  
18 edge of the shield to support the head, neck and the upper thorax when deployed under collision conditions. This  
19 anatomical micro air cushion ( 131) is supported by pairs of telescoping tubes the lower member of each such  
20 tubes being fixed to the harness/shield support in the vicinity of the sacrificial chamber, and the upper member of  
21 each pair of telescoping tubes are attached to the passive anatomical micro air cushion (131). The outer tubes  
22 have contoured semi-rigid materials to conform broadly to the body shape. The lower and upper members of  
23 each pair telescope into one another co-axially, and are lockable in different longitudinal positions relative to the  
24 other member of the pair, thereby providing for a variable height anatomical micro air cushion. Airflow under  
25 deployment conditions is conducted either directly through said telescoping tubes or separate tubes that have an  
26 “accordion” collapsible structure that can extend as the telescoping tubes do, and may be placed inside said  
27 telescoping tubes. The length of the telescoping tubes may be manually set with the locks or in other  
28 embodiments set by automated or computer controls that sense the size of the passenger from selected elements  
29 of the multi-element contoured seat.

30  
31 Yet another embodiment has a harness as in figure 12H2 except that there is a safety  
32 harness support arm only on the outer side of the passenger towards the side of the vehicle. (i.e in some of these  
33 embodiments there is one Safety Harness elbow (132), one Safety Harness extending upper arm (133) and  
34 one Safety Harness Pivoting lower arm (134). Moreover the safety harness/shield support arm is designed such  
35 that upon release from across the lap of the passenger, the shield flips to a vertical plane in the vicinity of the  
36 vertical plane of said support arm. Thereby permitting the safety harness to swing over the head of the passenger  
37 even when the seat is only partially displaced for entry or exit from the vehicle. Often this may be useful when  
38 there is limited access space next to the vehicle.

1 Yet another embodiment, principally for vehicles with drive by wire technologies, has the  
2 vehicle controls mounted on the shield . If a steering wheel is used this may be mounted on the front surface of  
3 the shield (on the surface opposite the passenger). The steering wheel or other controls may have distance  
4 adjustments for ergonomic positioning.

5 Yet another embodiment principally for drive by wire technologies , has the driver controls  
6 mounted on the contoured arm rests of the car. Adjustments for the arm rests will include further controls for the  
7 ergonomic positioning of these controls on the arm rests.

8 Vehicles, principally those that utilize drive by wire technologies with either of the above  
9 configurations, will have the entire area below the windshield free of controls. This embodiment utilizes this  
10 area for a GPS driven positioning display that mimics the view ahead of the driver. The display system may use  
11 vector imaging techniques or non-linear image mapping techniques that are well disclosed in the background art  
12 that provide the same perspective to the driver on the display as what he sees on the road ahead, thereby  
13 minimizing mental processing of information in establishing a correspondence between the image and the actual  
14 physical position and orientation of the vehicle thereby reducing reaction time for action by the driver.  
15 Furthermore, the positioning of the display just below the screen ensures that there is minimal spatial  
16 disorientation of the driver in turning his/her head to look at the screen thereby reducing further the mental  
17 information processing needs and improving further the reaction time of the driver. In some embodiments when  
18 there are controls such as a steering wheel in front of the driver, a fixed or a "pop up" screen just below the  
19 windshield or a projection onto the lower windshield may be utilized. The image may include the destination and  
20 path to that destination and may be at a different scale to the perspective of the driver ahead of the vehicle. This  
21 embodiment and variations provide a unique system that conventional GPS navigation systems do not provide in  
22 speeding up driver reaction times.

23  
24 Another embodiment has air conditioning micro-ducts on the seating surfaces and the  
25 safety harness/shields, for the comfort of passengers, particularly in open vehicles.

26  
27 Another alternative embodiment has the "Open" switch for the slide on the inside of the  
28 vehicle designed the "press bar" so that the intuitive reaction of the passenger to "open the door" is harnessed.  
29 However, this can be deactivated when the vehicle is in motion.

30 Another alternative embodiment has a center console that is designed to crush under  
31 impact as shown in Figures 1F – 4F, thereby minimizing the ejection of the far side passenger on impact.

32 Another alternative embodiment has the internal airbag partially filled at all times, so that  
33 in the event of no deployment of the external airbags either because of technology failure or non installation or  
34 other reason, the passenger and seat arrangement are cushioned even prior to further inflation of the internal  
35 airbag on deployment on impact. Shock absorbers may supplement the operation of the internal airbags in this  
36 embodiment with partially inflated internal airbags under normal operating conditions.

37 Another alternative embodiment can have the internal airbags deployed on impact as noted  
38 with such deployment effected by inflation by some of the compressed air of the external airbags on impact,  
39 thereby providing "acceleration de-amplification" for the movement of the passengers on impact.

1 Yet another embodiment has proactive sensors deploying the internal airbags directly,  
2 without the installation of external airbags.

3 Yet another embodiment of the invention has a retracting canopy stored in the roof of the  
4 vehicle, and attachable to the protector shield or attached components such as the side window, when desired.  
5 When attached, the canopy will deploy over the seats when in the extended or loading positions, thereby  
6 protecting the seat and the passenger from rain or other snow while entering or leaving the vehicle.

7 Yet another embodiment has external airbags constructed using the Passive Air-Cushion  
8 System with micro chambers that are connected to each other by restricted paths that provide visco elastic energy  
9 absorption in the event of some sections of the airbag being impacted while others are not, thereby forcing air  
10 from the compressed micro chambers to the other micro chambers, each of the micro chambers functioning as  
11 either a sacrificial chamber or a Micro Air Cushion on impact. This embodiment may of course have external  
12 airbags proactively deployed in the manner described herein, prior to impact and their performance as Micro Air  
13 Cushion systems. Yet another variation may include one-way valves between the chamber directly connected to  
14 the inflation source and each of the micro-chambers (implementable for example with flaps against an aperture )  
15 so that inflation may be achieved rapidly, and then the Passive Air-cushion benefits realized on impact.

16 Yet another embodiment uses the Passive Air-cushion system to protect passengers from  
17 "Whip Lash" injury, by providing Micro Air-cushions in the vicinity of the head and neck, and providing  
18 sacrificial chambers that are compressed in the event of a rear end collision. In some embodiments the sacrificial  
19 chamber can be mounted below the seat with one face mounted to the vehicle structure and the other face  
20 mounted to the seat of the passenger, the seat being mounted to the support structure to allow controlled limited  
21 rearward movement relative to its mountings to allow compression of the sacrificial chamber by the inertial mass  
22 of the passenger and seat on impact.

23 Yet another embodiment utilizes multiple adjoining but separate Passive Air-cushion  
24 systems where one such system connects the external airbags (sacrificial chambers) with internal airbags (micro  
25 Air-cushions), and another such system connects different and distinct internal airbags (sacrificial chambers) to  
26 micro Air-cushions in the vicinity of the passenger's body, thereby creating a cascading system of Passive Air -  
27 cushion systems. These embodiments may of course have external airbags proactively deployed in the manner  
28 described herein, prior to impact and their performance as Micro Air Cushion systems..

29 Yet another embodiment utilizes an auxiliary brake attached to the secondary slides in  
30 addition to the friction limited sliding arrangements of the secondary slide, to provide a further control on the  
31 rate of movement of the secondary slide under side or lateral impact.

32 Yet another embodiment utilizes a foot safety switch attached to the foot rest, that activates  
33 the sliding mechanism to move the sliding seats into and out of the vehicle. The foot rest in some such  
34 embodiments may be bar that is depressed to move the slide into and out of the vehicle. These foot rests being  
35 designed to avoid ankle injuries in the event of rear collisions sustained by the vehicle.

36 Yet another embodiment uses supplementary porous filling materials within prefilled  
37 internal airbags designed with suitable vents to change the compression characteristics of the inside airbags  
38 under impact.

1 Yet another embodiment utilizes pressure memory capable materials on the surface of the  
2 seats or passenger supports so that surround seats contour to the exact shape of the body for further comfort of  
3 passengers and also better support under collision conditions.

4 Yet another embodiment, has wheel chairs as passenger support mechanisms for the  
5 disabled, with collapsible wheels such that the chairs may be backed into clamps that attach on the lower side of  
6 the chair supports. In some such embodiments (as illustrated in figures 18A to 18 J) these clamps along with  
7 the lower cushion of the car seat 148 – (which is specially made to accommodate the chair support cross  
8 members), are extended forward on tertiary slides or extension arms with hydraulic automation, such that the  
9 movement forward and if necessary down, supports the wheel chair by locking the chair clamps 149 to the chair  
10 cross supports 150, and then providing adequate support for the passenger and the wheel chair. The Tertiary  
11 Slides or extension arm is supported by the impact decoupler/ Secondary Slides which are in turn attached to the  
12 Upper Primary Slides in the extended or loading position. Figure 18B illustrates the position of the seat bottom  
13 and clamps just below the wheel chair prior to attachment to the wheel chair. Once the hydraulic mechanism  
14 raises the wheel chair off the ground, the Primary Pivot of the rear wheels 151 may be unlocked and the wheel  
15 swung up backwards and locked as noted in Figure 18C. Notably the Rear wheels support much of the  
16 passenger weight when the wheel chair is used and therefore in addition to the pivoting Principal Rear Wheel  
17 Support 152 the rear wheel in addition has a Rear Wheel Support Strut 153 that supports the compressive load  
18 when the wheel chair is operational. Thereafter the front wheels may be unlocked and swung back on the Primary  
19 Pivots for the Front Wheel 157. This is illustrated in Figure 18 D.

20 Thereafter the space below the wheel chair is clear and the tertiary slide or arm mechanism  
21 can move the wheel chair back and lock it with and against the Seatback 156 which is specially shaped to  
22 accommodate the cross support members of the wheel chair. This is illustrated in Figure 18 E. Some such  
23 embodiments may have the option to release the rigid back support mounting of the wheel chair 158, and thereby  
24 benefit from the reclining options of the vehicle seat back. In the process of moving back to the seat back 156,  
25 the spring loaded locking sleeves 155, that support the Secondary pivot for rear wheel retraction 144 are pushed  
26 forward relative to the wheel chair body thereby releasing the Secondary Pivot for rear wheel retraction 154 to  
27 allow the wheels to swing in and lock behind the seat back 156. This is illustrated in Figure 18F. The wheel chair  
28 is then in a position on the extended impact decoupler/secondary slide to be transported into the vehicle. Notably  
29 in this wheel chair conversion embodiment, supplementary side and back air cushions may be inflated to fill in  
30 the areas where wheel chair support members are in the vicinity of the passenger and also to hold the wheel chair  
31 structure securely, thereby providing further protection in the event of a collision of the vehicle. This wheel chair  
32 conversion embodiment has all the side impact protection as the regular seat and has all the options for front  
33 impact protection of the safety shield/harness or more conventional options. Figure 18 G shows a plan view of  
34 the wheel chair prior to the insertion of Seat lower cushion and support structure. Figure 18 H illustrates an  
35 elevation view of the wheel chair and the seat lower cushion and support structure. Still other of these  
36 embodiments may use turn tables or other rotating mechanisms rather than the tertiary sliding arrangements or  
37 extending arms so that the wheel chair may be directly loaded on a turn table mounted on the impact  
38 decoupler/secondary slides, and then rotated into a driving or passenger position when retracted into the vehicle.

1 Yet another embodiment has anatomical micro-aircushions on the left and right edges of  
2 the support surface of the safety shield connected to selected sacrificial chambers along the bottom edge of said  
3 support surface. This will provide additional support for the passenger in a side impact, by assisting in  
4 preventing body movement outside the contoured seat under collision conditions.

5 Yet another embodiment has anatomical micro-aircushions on the outer edges of each of  
6 the contoured seats, particularly to cover a part of the front of the shoulders the legs and torso in the event of a  
7 side collision. These anatomical air-cushions use sacrificial chambers on the sides of the seats.

8 Yet another embodiment minimizes ejection hazards by controlling further the lateral  
9 movement of the seats under side impact. In these embodiments, the Upper primary slide is connected to the  
10 locking mechanisms that hold it to the vehicle under operating conditions through shock absorbers or spring  
11 mechanisms that allow controlled movement of the upper primary slides out of the vehicle when the vehicle  
12 sustains a side impact from the far side. In such embodiments the locks do not disengage when there is a side  
13 impact, as the shock absorbing devices provide the required controlled lateral movement of the far side upper  
14 primary slide under impact.

15 Yet another embodiment has a flexible stretchable (or folded) material that is bound to the  
16 protector shield and the “doors” of the vehicle on one of its edges where it makes contact normally with the  
17 vehicle body, the other edge of the flexible and stretchable material is bound to a frame that locks to the vehicle  
18 body under operating conditions. Under normal egress and ingress the frame along with the “doors” with the  
19 flexible, stretchable material operates as one unit the frame being held together with the “door” with door impact  
20 decouplers that fracture or disengage under impact, thereby allowing the “door” and the upper primary slide on  
21 the far side to extend out of the vehicle while the frame remains locked to the vehicle, and stretching the flexible,  
22 stretchable material so that passenger body extremities are not ejected from the vehicle but are retained by the  
23 flexible stretchable material within the vehicle.

24 Yet another embodiment has preinflated inside airbags that are deflated when seats move  
25 outwards (on the far side) under impact, thereby creating more space within the vehicle, minimizing the need for  
26 ejection on the far side under impact.  
27

## 28 CONCLUSIONS, RAMIFICATIONS & SCOPE

29 Thus it will become apparent that the present invention presented, provides a new  
30 paradigm for implementing key safety features and providing utility in accessing passenger vehicles and comfort  
31 in travelling in such vehicles. While the above description provides many specificities, these should not be  
32 construed as limitations on the scope of the present invention, but rather as an exemplification of the preferred,  
33 an additional and an alternative embodiment thereof. Many other variations are possible.

34 The present invention provides an arrangement that diverts the impact energy in lateral or  
35 side impacts away from the passengers to the remaining mass of the vehicle thereby protecting the passengers but  
36 decelerating the impacting object with the remaining mass of the vehicle. Moreover the arrangement  
37 synergistically provides a means for utilitarian easy access to the vehicle for passengers and drivers alike and  
38 allows the installation of multi-element surround contoured seats for the comfort and protection of passengers.  
39 Furthermore, the arrangement allows the installation of a new and unique safety harness that may obviate the

1 need for safety belts and front impact airbags for protection in head-on collisions. This arrangement differs  
2 sharply from the Background art in that it does not simply offer to the impacting body a reinforced rigid shell  
3 where the passenger is treated as part of this integral unit, but rather provides selective and differential treatment  
4 of the mass of the passengers and driver of the vehicle vis-à-vis the remaining mass of the vehicle. Furthermore  
5 the present invention differs sharply from the Background art in that the resulting structure synergistically  
6 permits the installation of contoured multi-element surround seats that would not be implementable without the  
7 slide arrangements on either side of the vehicle in the present invention.

8                 The present invention provides a gravity slide drive for my arrangement for which there is  
9 no counterpart in the Background art. This allows further Utility and weight and energy saving in implementing  
10 the above elements of the present invention.

11                 The present invention includes External side Airbags that differ sharply from the  
12 Background art in that for the first time they proactively create a “Just in Time” deceleration zone for the lateral  
13 or side impact with internal and/or external side airbags while not remaining in an extended position under  
14 normal operating conditions of the vehicle.

15                 The present invention describes an indo-skeletal structure of the vehicle body that permits  
16 the energy transfer from the lateral or side impact through compressive members to the body of the vehicle.  
17 Unlike the Background art this indo-skeletal structure is designed to transfer energy to the body of the vehicle  
18 without transferring it to the passengers and driver of the vehicle. The passengers are targeted for protection with  
19 “Safety zones”.
